

A Survey of Computational Assumptions on Bilinear and Multilinear Maps

Allison Bishop

IEX and Columbia University

Group Basics

*“There are two kinds of people in this world. Those who like additive group notation, and those who like **multiplicative group notation.**”*

$$g, g^a, g^b, g^{a+b}$$

inefficient:
discrete log

Bilinear Groups

efficient:

$$g, a \rightarrow g^a$$

$$g^a, g^b \rightarrow g^{a+b}$$

$$g^a, g^b \rightarrow e(g, g)^{ab}$$

When Faced with a New Group Assumption:

Is it secret?
Is it safe?

Is it useful?
Is it needed?

Kinds of Assumptions

- Generic group models
- q-type assumptions
- static assumptions

Variants:

Symmetric/Asymmetric

Composite Order/ Prime Order

Linear/ Bilinear/ MultiLinear

Kinds of Proof Techniques

- Brute Force basic generic group arguments
- Cancelation BB IBE
- Encoding G06, W'05 ...
- Dual System W09, LW10, LOSTW10,...
- Deja Q CM14, W16
- ...

Bilinear Diffie-Hellman Assumption

Symmetric group:

$$g \in G, e : G \times G \rightarrow G_T$$

Given:

$$g, g^x, g^y, g^z$$

Distinguish:

$$e(g, g)^{xyz} \text{ from } e(g, g)^r$$

SXDH Assumption

Asymmetric group:

$$g \in G, h \in H, e : G \times H \rightarrow G_T$$

Given:

$$g, h, g^a, g^b$$

Distinguish:

$$g^{ab} \text{ from } g^r$$

A Basic q-type Assumption

Symmetric group:

$$g \in G, e : G \times G \rightarrow G_T$$

Given:

$$g, g^s, g^a, g^{a^2}, g^{a^3}, \dots, g^{a^q}$$

Distinguish:

$$e(g, g)^{sa^{q+1}} \text{ from } e(g, g)^r$$

A Driving Example: IBE

$$PP : g, g^a, g^b, e(g, g)^\alpha$$

$$CT : M e(g, g)^{\alpha s} \quad g^s \quad g^{s(aID+b)}$$

$$SK : \quad g^{\alpha+r(aID+b)} \quad g^r$$

Decryption:

$$e(g, g)^{\alpha s + sr(aID+b) - sr(aID+b)}$$

$$= e(g, g)^{\alpha s}$$

Arguing Generic Security

Look at exponents you are given in G:

Look at the blinding factor:

$$\alpha s$$

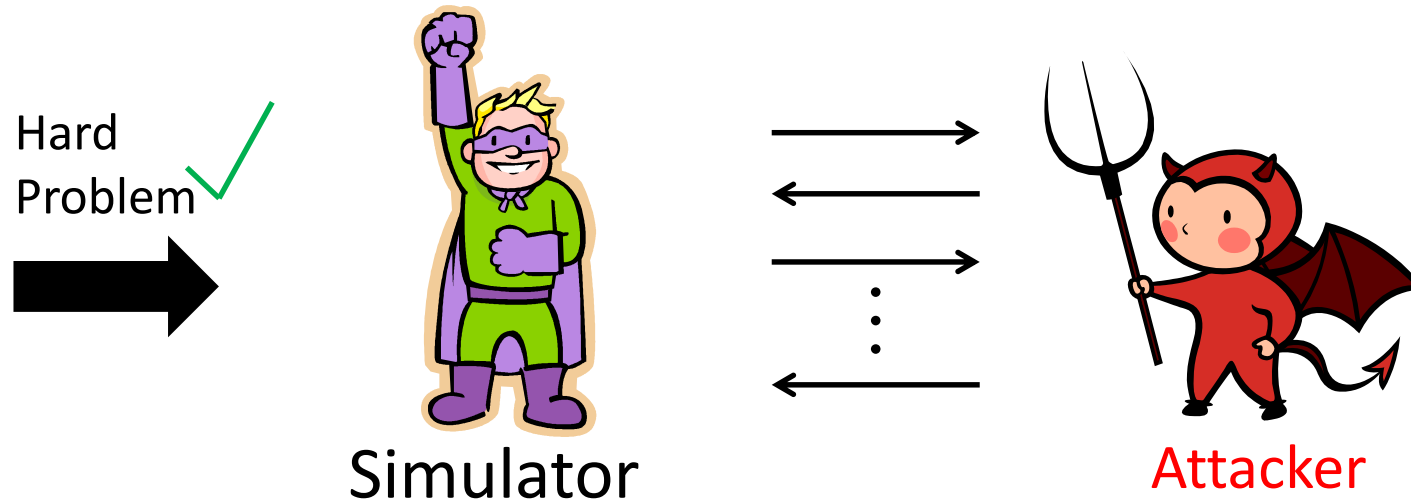

$$a, b, s, s(aID^* + b),$$

$$\alpha + r_1(aID_1 + b), r_1, \dots, \alpha + r_q(aID_q + b), r_q$$

All you can do is take linear combinations of degree at most 2

No way to get αs alone when $ID^* \neq ID_i \forall i$

Proof Challenges Beyond Generic Security

Simulator must balance two competing goals:

answer
attacker
queries

leverage
attacker
success

Arguing Selective Security

- Embed the challenge as a function of known ID^*

$$\alpha = xy, s = z$$

$$a = x, b = -xID^* + w$$

Given:

$$g, g^x, g^y, g^z$$

Distinguish:

$$e(g, g)^{xyz} \text{ from } e(g, g)^r$$

$$PP : g, g^a = g^x, g^b = (g^x)^{-ID^*} g^w, e(g, g)^\alpha = e(g^x, g^y)$$

$$CT : g^s = g^z, g^{s(aID^* + b)} = (g^z)^w$$

$$\text{Choose } r = -\frac{y}{ID - ID^*} + r'$$

$$\text{then } \alpha + r(aID + b) = xy - xy + rw = rw$$

Simulator can produce key for any ID not equal to ID^ !*

How to Leverage a q -Type Assumption [example from W05]

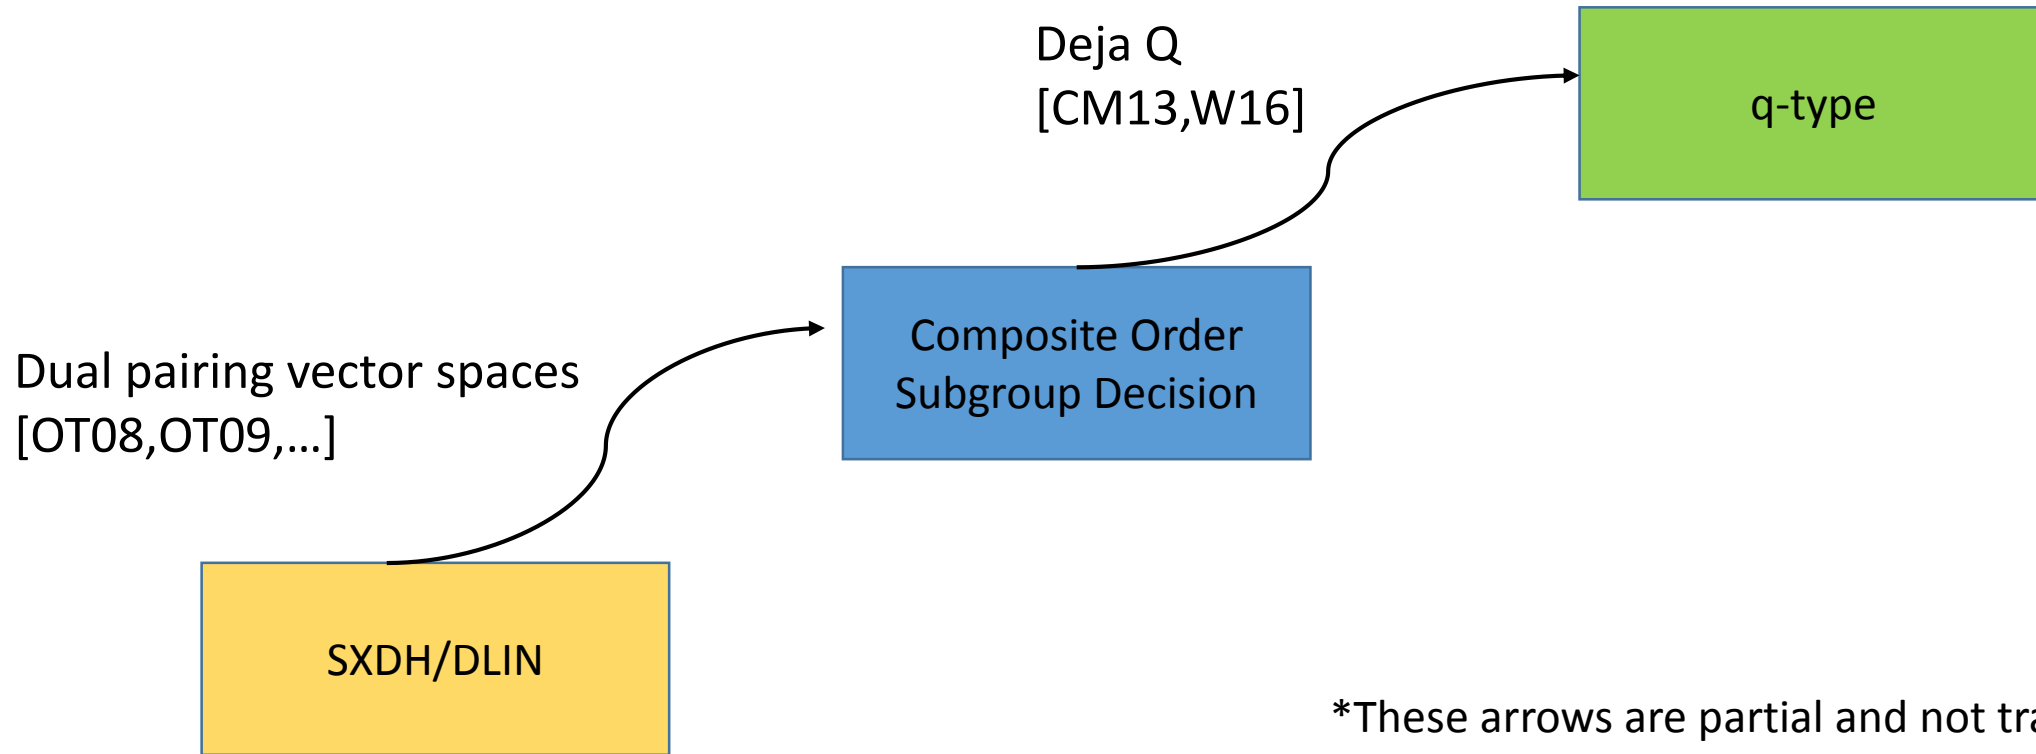

What if we don't want to fix ID^* ahead of time?

To partition small PP with parameter q :
Use a q -size assumption!

Simulation Techniques

*These arrows are partial and not transitive!

Composite Order Bilinear Groups

How the pairing operates:

Dual Pairing Vector Spaces

$$b_1, b_2 \leftarrow \mathbb{Z}_p^d$$

$$b_1^*, b_2^* \text{ s.t. } b_i \cdot b_j^* = 0 \text{ if } i \neq j,$$

$$b_i \cdot b_i^* = 1$$

Emulates some features of composite order, asymmetric group:

$$g^{rb_1 + tb_2}$$

$$g^{sb_1^* + zb_2^*}$$

$$e(g, g)^{rs + tz}$$

Emulating Subgroup Decision using SXDH

Asymmetric group: $g \in G, h \in H, e : G \times H \rightarrow G_T$

Given:

$$g, h, g^a, g^b$$

$$b_1 := ax_1 + x_2 \quad b_2 := x_2$$

$$b_1^* = a^{-1}x_1^* \quad b_2^* = x_2^* - ax_1^*$$

Distinguish:

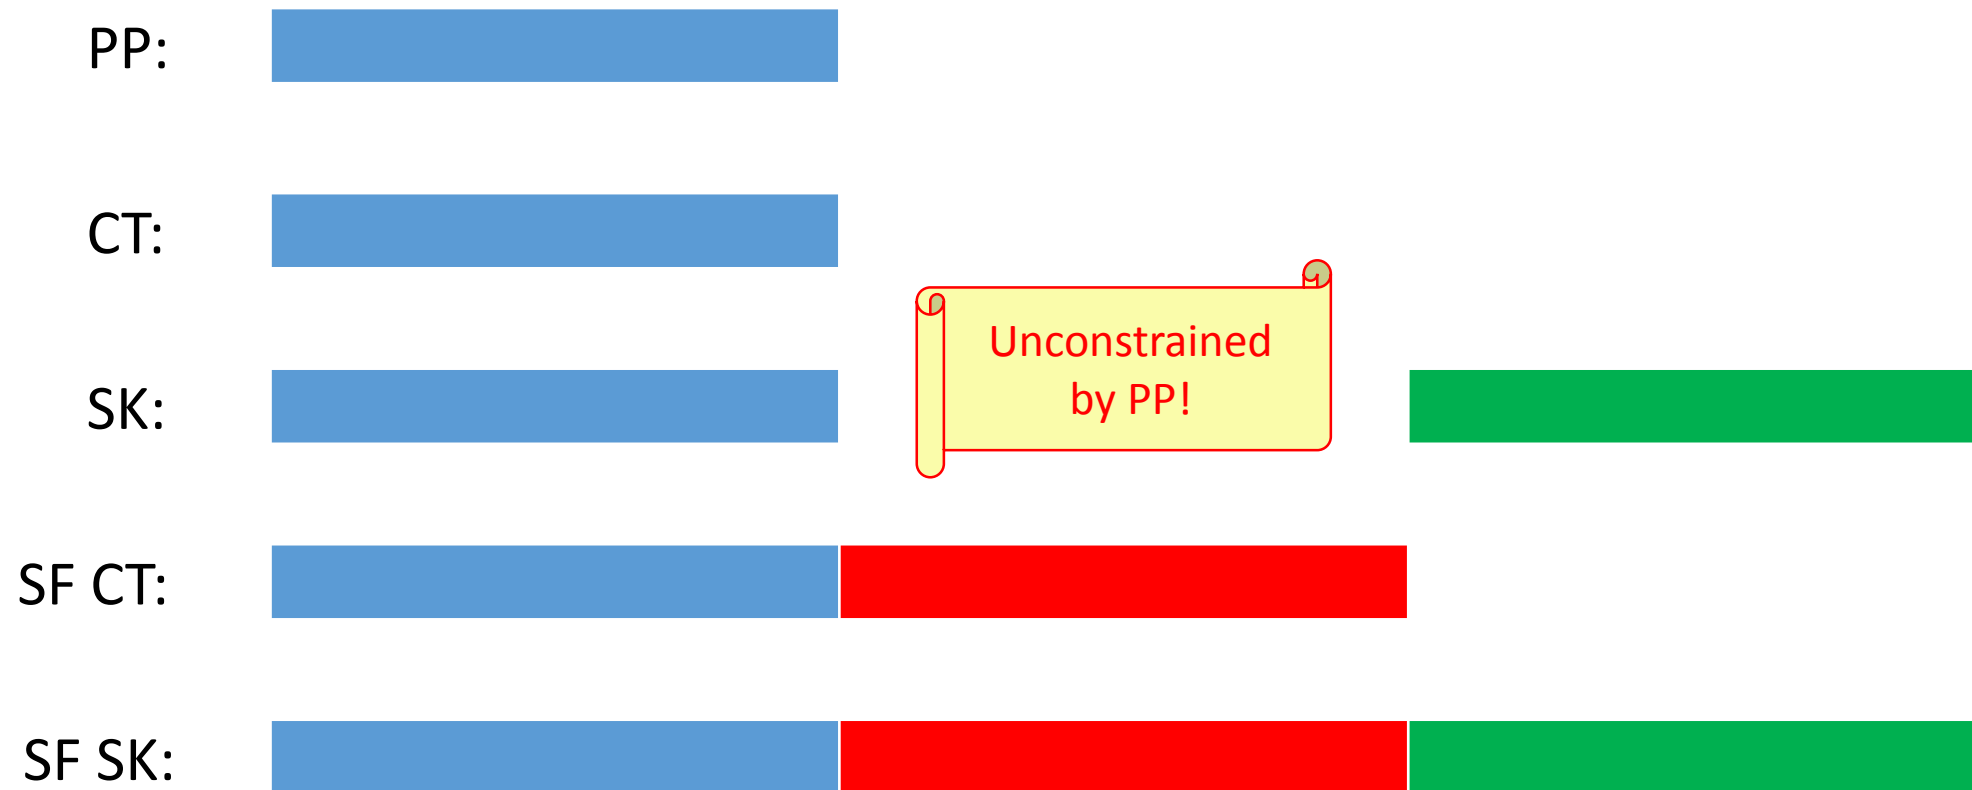

$$g^{ab} \text{ from } g^r$$

can make g^{b_1}, g^{b_2}

can make $h^{rb_1^*}$, not $h^{rb_2^*}$

Dual System – Using Subgroup Assumptions for Functional Encryption [W09 + too many to cite*]

Most Basic Template:

Using Subgroup Assumptions for Obfuscation [GBSW 15]

- Reduction will *isolate* each input.
- Main idea:
 - Have poly many “parallel” obfuscations, each responsible for a bucket of inputs
 - Hybrid Type 1: Allocate/Transfer inputs among different buckets, *but* programs do not change at all.
Assumption used here.

Ok So what are these buckets really like?

Simple example:

Want to implement:

$$F(x_1, x_2) = \text{XOR}(x_1, x_2)$$

$$M_{1,0} = \begin{array}{c} \text{æ} \\ \text{ç} \\ \text{è} \end{array} \begin{array}{cc} 1 & 0 \\ 0 & 1 \end{array} \begin{array}{c} \ddot{\text{o}} \\ \ddot{\text{v}} \\ \emptyset \end{array}$$

$$M_{1,1} = \begin{array}{c} \text{æ} \\ \text{ç} \\ \text{è} \end{array} \begin{array}{cc} 0 & 1 \\ 1 & 0 \end{array} \begin{array}{c} \ddot{\text{o}} \\ \ddot{\text{v}} \\ \emptyset \end{array}$$

$$M_{2,0} = \begin{array}{c} \text{æ} \\ \text{ç} \\ \text{è} \end{array} \begin{array}{cc} 1 & 0 \\ 0 & 1 \end{array} \begin{array}{c} \ddot{\text{o}} \\ \ddot{\text{v}} \\ \emptyset \end{array}$$

$$M_{2,1} = \begin{array}{c} \text{æ} \\ \text{ç} \\ \text{è} \end{array} \begin{array}{cc} 0 & 1 \\ 1 & 0 \end{array} \begin{array}{c} \ddot{\text{o}} \\ \ddot{\text{v}} \\ \emptyset \end{array}$$

$$B = \begin{array}{c} \text{æ} \\ \text{ç} \\ \text{è} \end{array} \begin{array}{cc} 0 & 1 \\ 1 & 0 \end{array} \begin{array}{c} \ddot{\text{o}} \\ \ddot{\text{v}} \\ \emptyset \end{array}$$

[Barrington]: All log-depth (NC^1) circuits
have poly-size Matrix Branching Programs

Towards Obfuscation

Kilian Simulation

- Oblivious Matrix Branching Program for F :
 - n -bit input $x = x_1 x_2 \dots x_n$ (e.g. $n = 2$ here)
 - $2k$ invertible matrices over Z_N
 - Evaluation on x :

$$\tilde{O} = \prod_{i=1}^k M_{i, x(i \bmod n)} = \begin{cases} I & \text{if } F(x) = 0 \\ B & \text{if } F(x) = 1 \end{cases}$$

- Where B is fixed matrix $\neq I$ over Z_N
- Kilian Randomization:
 - Chose R_1, \dots, R_{k-1} random over Z_N

- Kilian shows that for each x , can **statistically** simulate M_x matrices knowing only product.

Hybrids Intuition
